

AN UPPER BOUND FOR THE DAVENPORT CONSTANT OF C_n^3

MAX GRINSZTAJN

ABSTRACT. Let $D(G)$ denote the Davenport constant of a finite abelian group G , and let C_n denote a cyclic group of order n . For $n \geq 2$, put

$$P(n) = \max_{p^a \parallel n} p^a,$$

the largest primary component of n . We prove the pointwise bound

$$D(C_n^3) \leq 4n - P(n) - 2.$$

In particular, the normalized supremum

$$S := \sup_{n \geq 2} \frac{D(C_n^3) - 1}{n - 1}$$

satisfies $S \leq 4$, improving the known uniform upper bound $S \leq 20369$ due to Zakarczemny [5]. The conjectural value remains $S = 3$. The proof combines known local zero-sum estimates over C_p^3 with an induction over the prime factors of $n/P(n)$, starting from the largest primary component of n . The proof was discovered with assistance from GPT-5.5 Pro. The deduction from the cited results in the literature was also checked in a conditional Lean 4 formalization with Aristotle [7].

1. INTRODUCTION AND NOTATION

Throughout, all finite abelian groups are written additively. For a finite abelian group G , the Davenport constant $D(G)$ is the least integer N such that every sequence over G of length at least N contains a non-empty zero-sum subsequence. For $k \geq 1$, let $D_k(G)$ be the least integer N such that every sequence over G of length at least N contains k pairwise disjoint non-empty zero-sum subsequences. Finally, $\eta(G)$ denotes the least integer N such that every sequence over G of length at least N contains a non-empty zero-sum subsequence of length at most $\exp(G)$.

We write C_n^3 for $C_n \oplus C_n \oplus C_n$. The main result is the following.

Theorem 1.1. *For every integer $n \geq 2$,*

$$D(C_n^3) \leq 4n - P(n) - 2, \quad P(n) = \max_{p^a \parallel n} p^a.$$

Consequently, $D(C_n^3) \leq 4(n - 1)$ for every $n \geq 2$.

In particular, if

$$S := \sup_{n \geq 2} \frac{D(C_n^3) - 1}{n - 1},$$

then Theorem 1.1 gives $S \leq 4$. The known uniform upper bound is $S \leq 20369$, coming from the estimate

$$D(C_n^3) \leq 20369(n - 1) + 1$$

of Zakarczemny [5]. The standard lower bound gives $S \geq 3$ [4], and the conjectural pointwise formula is

$$D(C_n^3) = 3(n - 1) + 1 \quad (n \geq 2),$$

which is equivalent to $S = 3$ [4]. Thus the result below improves the known interval from $3 \leq S \leq 20369$ to

$$3 \leq S \leq 4.$$

Date: May 2026.

The proof uses the inductive method for generalized Davenport constants, together with local estimates for $D_k(C_p^3)$. We shall use the following standard facts from zero-sum theory. If

$$G \simeq C_{n_1} \oplus \cdots \oplus C_{n_r}, \quad 1 < n_1 \mid \cdots \mid n_r,$$

then

$$D(G) \geq D^*(G) := 1 + \sum_{i=1}^r (n_i - 1),$$

and equality holds when G is a p -group; see Gao–Geroldinger [4]. Applying this to $C_{p^a}^3$ gives

$$D(C_{p^a}^3) = 3p^a - 2.$$

The same lower bound applied to C_m^3 gives

$$D(C_m^3) \geq 3m - 2.$$

Thus, in the sequel, we shall use

$$(1) \quad D(C_{p^a}^3) = 3p^a - 2, \quad D(C_m^3) \geq 3m - 2.$$

2. AUXILIARY ESTIMATES

We first record two consequences of the definitions.

Lemma 2.1 (Inductive method). *Let $H \leq G$ be finite abelian groups. Then*

$$D(G) \leq D_{D(H)}(G/H).$$

Proof. Let S be a sequence over G of length at least $D_{D(H)}(G/H)$, and let $\bar{S}$ be its image in G/H . By the definition of $D_{D(H)}(G/H)$, the sequence $\bar{S}$ contains $D(H)$ pairwise disjoint non-empty zero-sum subsequences. Lifting them to subsequences $T_1, \dots, T_{D(H)}$ of S , their sums lie in H . The sequence $\sigma(T_1), \dots, \sigma(T_{D(H)})$ over H has a non-empty zero-sum subsequence. The union of the corresponding T_i 's is a non-empty zero-sum subsequence of S . $\square$

Lemma 2.2 (Extraction lemma). *Let G be a finite abelian group, let $e = \exp(G)$, and let $j \geq 1$. Assume that $\eta(G) \leq M$ and $D_j(G) \leq M$. Then, for every $k \geq j$,*

$$D_k(G) \leq M + e(k - j).$$

Proof. Let S be a sequence over G of length at least $M + e(k - j)$. Repeatedly using $\eta(G) \leq M$, we may remove $k - j$ pairwise disjoint non-empty zero-sum subsequences, each of length at most e . The remaining sequence has length at least M , hence contains j further pairwise disjoint non-empty zero-sum subsequences. Altogether S contains k such subsequences. $\square$

The following local estimate packages the known zero-sum results over C_p^3 that are needed in the proof.

Lemma 2.3 (Local estimate). *For every prime p and every $k \geq 3p - 2$,*

$$D_k(C_p^3) \leq pk + p^2.$$

Proof. For $p = 2$, Freeze–Schmid record that $D_0(C_2^3) = 3$ and $k_D(C_2^3) = 2$ in their asymptotic notation [3]. Thus

$$D_k(C_2^3) = 2k + 3 \quad (k \geq 2),$$

and the desired estimate follows from $2k + 3 \leq 2k + 4$.

For $p = 3$, Bhowmik–Schlage-Puchta prove that every sequence of length 15 over C_3^3 contains three disjoint zero-sum subsequences [1]; this input is also cited in their later paper, where they use $\eta(C_3^3) = 17$ [2]. Hence $D_3(C_3^3) \leq 17$. Applying Lemma 2.2 with $M = 17$ and $j = 3$, we get, for all $k \geq 3$,

$$D_k(C_3^3) \leq 17 + 3(k - 3) = 3k + 8 \leq 3k + 9.$$

For $p = 5$, the same paper gives $\eta(C_5^3) = 33$ and shows that every sequence of length 33 over C_5^3 contains three disjoint zero-sum subsequences [2]. Thus $D_3(C_5^3) \leq 33$, and Lemma 2.2 gives, for all $k \geq 3$,

$$D_k(C_5^3) \leq 33 + 5(k - 3) = 5k + 18 \leq 5k + 25.$$

It remains to consider $p \geq 7$. Put

$$M = (p + 1)(3p - 7) + 4 = 3p^2 - 4p - 3.$$

By Bhowmik–Schlage-Puchta [2],

$$(2) \quad \eta(C_p^3) \leq M,$$

and, for every $j \geq 1$,

$$(3) \quad D_j(C_p^3) \leq \max \left\{ 5p - 2, \frac{3(p-1)}{2}j + 2p + 5 \right\}.$$

Set

$$x = \frac{M - 2p - 5}{\frac{3}{2}(p-1)} = \frac{2(3p^2 - 6p - 8)}{3(p-1)}, \quad j_0 = \lfloor x \rfloor.$$

Since $p \geq 7$, we have $5p - 2 \leq M$. Also, by the definition of j_0 ,

$$\frac{3(p-1)}{2}j_0 + 2p + 5 \leq M.$$

Therefore (3) gives $D_{j_0}(C_p^3) \leq M$. Moreover $j_0 < 2p < 3p - 2$. Finally, since $j_0 \geq x - 1$,

$$pj_0 + p^2 \geq p(x - 1) + p^2 = M + \frac{3p^2 - 16p - 9}{3(p-1)} \geq M,$$

the last inequality again following from $p \geq 7$. Now let $k \geq 3p - 2$. Then $k \geq j_0$, and Lemma 2.2, together with (2) and $D_{j_0}(C_p^3) \leq M$, gives

$$D_k(C_p^3) \leq M + p(k - j_0).$$

Using $M \leq pj_0 + p^2$, we obtain

$$D_k(C_p^3) \leq pj_0 + p^2 + p(k - j_0) = pk + p^2.$$

This proves the lemma in all cases. □

3. PROOF OF THE MAIN THEOREM

Let $n \geq 2$, and put

$$Q = P(n).$$

By definition, Q is a prime-power divisor of n . Factor the remaining part of n as

$$n = Qp_1p_2 \cdots p_s,$$

where $p_1, \dots, p_s$ are primes, counted with multiplicity. Since Q is the largest primary component of n , each $p_i \leq Q$. Put

$$m_0 = Q, \quad m_i = Qp_1 \cdots p_i \quad (1 \leq i \leq s).$$

We prove by induction on i that

$$(4) \quad D(C_{m_i}^3) \leq 4m_i - Q - 2.$$

For $i = 0$, the integer $m_0 = Q$ is a prime power. Hence (1) gives

$$D(C_Q^3) = 3Q - 2 = 4Q - Q - 2,$$

which is (4) for $i = 0$.

Assume (4) for $m = m_{i-1}$, and write $p = p_i$. The group C_{pm}^3 contains a natural subgroup $H \simeq C_m^3$, with quotient $C_{pm}^3/H \simeq C_p^3$. By Lemma 2.1,

$$D(C_{pm}^3) \leq D_{D(C_m^3)}(C_p^3).$$

Furthermore, by (1),

$$D(C_m^3) \geq 3m - 2 \geq 3p - 2,$$

since $m \geq Q \geq p$. Lemma 2.3, applied with $k = D(C_m^3)$, yields

$$D(C_{pm}^3) \leq pD(C_m^3) + p^2.$$

Using the induction hypothesis,

$$D(C_{pm}^3) \leq p(4m - Q - 2) + p^2.$$

It remains to compare this with $4pm - Q - 2$. The required inequality is

$$p^2 - 2p + 2 \leq (p - 1)Q.$$

Since $Q \geq p$,

$$(p - 1)Q \geq p(p - 1) = p^2 - p \geq p^2 - 2p + 2$$

for every prime $p \geq 2$. Therefore

$$D(C_{pm}^3) \leq 4pm - Q - 2,$$

which proves the induction step.

Taking $i = s$, we have $m_s = n$, and hence

$$D(C_n^3) \leq 4n - Q - 2 = 4n - P(n) - 2.$$

Since $P(n) \geq 2$, this implies

$$D(C_n^3) \leq 4n - 4 = 4(n - 1).$$

This proves Theorem 1.1.

4. CONCLUSION

We have shown that

$$S = \sup_{n \geq 2} \frac{D(C_n^3) - 1}{n - 1} \leq 4.$$

This improves the known uniform upper bound $S \leq 20369$ to $S \leq 4$. The conjectural value $S = 3$, equivalent to the pointwise formula

$$D(C_n^3) = 3(n - 1) + 1 \quad (n \geq 2),$$

remains open.

5. REMARK ON FORMAL VERIFICATION

A conditional Lean formalization of the deduction in this note is available in [6]. The formalization assumes, as external axioms, the zero-sum inputs cited above: the standard p -group formula and lower bound, the inductive method, and the local estimates over C_p^3 . It checks the global induction and the resulting pointwise estimate of Theorem 1.1.
